Cancer survivors experience significant ongoing health problems, primarily as a result of cancer treatment and are vulnerable to high cancer-related symptom burden including psychological and physical symptoms, which linger long after treatment completion. These symptoms can be both a barrier to the adoption of healthy lifestyle behaviors and are an important intervention target. Adopting healthier behaviors may result in an immediate benefit of reduced symptom burden with the long-term benefit of improved health and reduced cancer risk. This presentation will examine the prevalence of symptoms and adoption of healthy lifestyle behaviors in ovarian cancer survivors participating in the Lifestyle Intervention for Ovarian cancer Enhanced Survival (LIVES) Study as well as present preliminary findings from the Nuestra Salud Study, a symptom management and lifestyle intervention for Latina cancer survivors and their caregivers.
